# Aviation Accident Analysis: Identifying Low-Risk Aircraft Options

Author: [Lewis Mwaki](#)

## Overview

This project analyzes historical aviation accident data to identify low-risk aircraft options for a company entering the aviation industry. By analyzing over 80,000 incidents spanning several decades, the project identifies specific aircraft models, engine configurations, and operational types that demonstrate superior safety profiles. This data-backed analysis provides actionable recommendations to the Head of Aviation Division, enabling confident and informed investment decisions that prioritize safety while meeting business objectives.

## Business Problem

Our company is venturing into aviation with no prior experience in the industry or knowledge of aircraft models. This presents significant risk both to our capital investments and, more importantly, to the lives of our customers and personnel. The Head of the Aviation Division needs data-driven insights to guide aircraft acquisition decisions, focusing on identifying models with proven safety records that align with our operational needs.

## Data

The analysis uses the NTSB Aviation Accident Database, one of the most comprehensive aviation incident datasets available. Key features include:

- Historical records spanning from 1923 to 2022
- Over 82,000 distinct accident records
- 31 data columns including aircraft specifications, weather conditions, injury severity, and flight purpose
- US-based incidents, providing consistency in reporting standards

Data source: [Aviation Accident Database on Kaggle](https://www.kaggle.com/datasets/asf2022/ntsb-aviation-accident-database)

## Methods

This report details the methodology used to analyze aircraft safety data, including data sources, analysis techniques, and validation procedures.

README

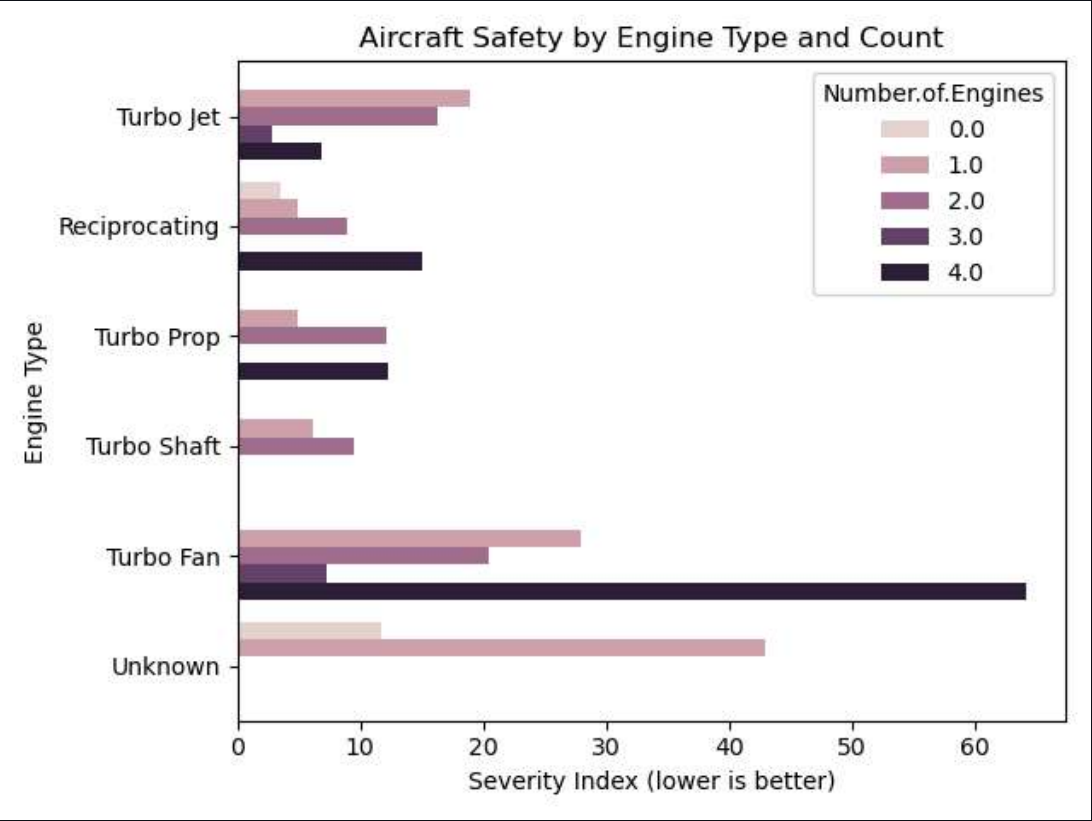

- Comparative analysis across engine types, aircraft models, and operational purposes
- Weather condition performance analysis (IMC vs. VMC)
- Visualization of safety metrics to identify patterns and outliers

## Results

Analysis revealed clear patterns in aircraft safety profiles across different configurations and conditions:

### Engine Type Safety Analysis

The analysis showed that certain engine configurations consistently demonstrate better safety records:

### Aircraft Performance in Different Weather Conditions

Some aircraft models showed remarkable resilience in challenging weather conditions:

1. **Prioritize specific engine configurations:** Three-engine turbojets and single-engine reciprocating configurations demonstrated the lowest risk profiles across multiple metrics.
2. **Match aircraft to operational purpose:** Models like Cessna 180/185 series and Piper PA-28 variants show excellent safety records for personal and instructional use, while other models are better suited for specialized operations.
3. **Consider weather resilience in acquisition decisions:** If operations will take place in regions with frequent IMC (Instrument Meteorological Conditions), select models that demonstrate superior performance in these conditions, such as certain Beechcraft and Cessna models.

## Next Steps

To build upon this analysis and continue developing our aviation strategy:

- **Develop specialized pilot training programs** tailored to our selected aircraft and flight purposes
- **Analyze additional risk factors** beyond those covered in this study
